### ABSTRACT

This study aimed to find out the effect of ultrasound in detected congenital anomalies, and perinatal outcomes and 150 patients were divided into two groups (90 patients diagnosed with ultrasound with an average age of  $30.9 \pm 5.5$  years) (60 cases were a control group with an average age of  $29.5 \pm 4.2$ ).

In this study, information received between January 1, 2019, and December 31, 2020, was used as databases of different hospitals in Iraq, Department of Obstetrics and Gynecology, which maintains a record of all newborns that show one or more congenital anomalies and statistical analysis was performed using IBM SOFT SPSS 22 for Windows, and the final document was prepared with Microsoft Office package.

The results that found in this study were Encephalocele 3 (3.3%) for the ultrasound group, 2 (3.3) for the control- Ventriculomegaly for the ultrasound group, 7 (7.8), 4 (6.7) for the control, Anencephaly for 5 (5.5) and over the control group was 1 (1.7), Posterior fossa cyst with 4 (4.4) for the ultrasound patient while for the control group it was 1 (1.7), Hydrops fetalis for ultrasound group 6 (6.7) and 2(3.3%) for the control group.

In this study, the logistic analysis and ultrasound diagnosis showed a direct relationship between them in the detection of congenital malformations, and this reveals the great role to the value of the diagnosis used in our current study.

Ultrasound, Detected, Encephalocele, Posterior, Perinatal, Diagnosis.

### Introduction

Congenital malformations have a significant impact on infant morbidity and mortality [1,2]. They are the first cause of infant mortality in countries which managed to reduce mortality from infectious and perinatal causes. Its spread worldwide is estimated at between (4-9) births in Iraq. In 2016, congenital anomalies and chromosomal abnormalities were the second cause of death among live births, with 120 deaths due to infant mortality since the 1970s [3,4,5]. Hypertensive disorders of pregnancy affect up to 10% of pregnant women, and the combined global incidence of pre-eclampsia

(PE) is approximately 3% 2. There are significant differences between developed and developing countries—development, which may be attributed to real differences or the data collection process. [6,7,8] PE and its complications are the major causes contributing to maternal and fetal morbidity and mortality worldwide since the procedures were implemented. [9]

During the perinatal period, for its diagnosis and management, a patient with a rare disease requires a multidisciplinary approach that includes, in addition to the obstetrician,

geneticists, radiologists, pediatric surgeons, [10]neonatologists, and psychologists, among others. Without this approach, diagnosis, management, and counselling becomes extremely difficult and even poorer. Prenatal evaluation is the first approach for a fetal defect. [11]

At this stage, the most likely diagnosis and aetiology are approached, along with a follow-up plan and method of delivery. Although most defects do not include prenatal treatment, preparing the medical team to receive a newborn with problems is one of the elements that improve the postpartum condition and facilitate future care. [12]

Part of the diagnostic task includes imaging studies such as ultrasound and MRI. It is in this area where teamwork between the obstetrician and radiologist becomes important to reach a joint diagnosis. A chromosome study involves a sample of tissue, either a chorionic biopsy, amniotic fluid, or fetal blood. [13]

Until recently, the karyogram was able to demonstrate major structural defects of chromosomes such as trisomy, deletion, duplication, and translocation. In recent years, technological advances in microarray technology have allowed the detection of small deletions or small variants from the scheme of care responsible for rare genetic syndromes. [14]

## **Patient and method**

### **Collection sample**

Data on patients were collected from different hospitals in Iraq, where a cross-sectional study was conducted on Iraqi patients between the ages of 20-40 years to know the effect of ultrasound in detecting congenital anomalies and perinatal outcomes.

Congenital malformations have gained relative importance in neonatal diseases requiring hospitalization in the special care unit for

antenatal check-ups, which are performed in a structured manner.

### **Methodology**

In this study, information received between January 1, 2019, and December 31, 2020, was used as databases of different hospitals in Iraq, Department of Obstetrics and Gynecology, which maintains a record of all newborns that show one or more congenital anomalies.

A special file is prepared for all newborns with congenital defects, in which the history of mothers, pregnancy, childbirth, and children is recorded. The vital diagnosis of hospitalization of the deformed patient is considered with regard to what the deformity means in terms of survival and the individual's integration into normal life. And was estimated the day of hospitalization for the deformed patient as the fact of his admission to the hospital.

In this study, ultrasound was relied upon by perinatologists and radiologists

Ultrasound examination is performed using a black and white (2D) probe. Depending on the quality of the device used, a good two-dimensional section quality makes the examination easier. A three- or four-dimensional (2D / 2D) ultrasound examination is used depending on the site, especially in the diagnosis of superficial anatomy and congenital anomalies.

A questionnaire was designed by experts from the Infertility Technical Group of the Ministry of Public Health, and a database was created using Microsoft Access; statistical analysis was performed using IBM SOFT SPSS 22 for Windows, and the final document was prepared with the Microsoft Office package.

Absolute frequencies were calculated for qualitative, prevalence, quantitative variables, mean and standard deviation, with 95% confidence intervals expected in all cases.

## Results

### Discussion

In this study, a cross-sectional study was conducted on Iraqi patients to know the effect of ultrasound in detecting congenital anomalies and perinatal outcomes.

Where the average age ranged from 20-40 years for both groups, and it was noted that the average body mass index increased to the older ages.

The prevalence of comorbidities was noted in this study, especially obesity, for 34 patients in the ultrasound group and 21 patients in the control group, as shown in Table 1.

while Evaluation of congenital malformations in groups of patients who underwent ultrasound and control the results, which found Encephalocele 3 (3.3%) for the ultrasound group,

2 (3.3) for control- Ventriculomegaly for ultrasound group 7 (7.8), 4 (6.7) for control, Anencephaly for 5 (5.5), and over the control group was 1 (1.7), Posterior fossa cyst with 4 (4.4) for the ultrasound patient while for the control group it was 1 (1.7)

Before the widespread use of obstetric ultrasound, most fetal abnormalities were known only at the time of birth, and from then on, the pediatrician and obstetrician began to search for causative factors, trying to provide parents with an explanation, step, and prediction. Currently, ultrasound has made it possible to identify, sometimes at an early stage, a large number of fetal anomalies, in

addition to changes in the volume of amniotic fluid, conditions associated with fetal structural disorders, or genetic abnormalities.

*The current study included 25 cases in the ultrasound group and 11 control group of congenital malformations that were detected; this frequency does not reveal the real occurrence of the problem in our environment because despite the spread of the study in primary care centers and in all ultrasound centers of the first level, perhaps not all patients with suspected fetal abnormalities were referred to the study cohort; In addition, many patients with a malformed fetus at the time of delivery did not receive an ultrasound assessment during pregnancy or did not receive prenatal care.*

*Due to the characteristics of this study, the specificity of the technique could not be accounted for, which is limited ourselves to defining the relationship between prenatal ultrasound findings and neonatal outcomes.*

*We classify this association as complete, partial, or none, as the full association was achieved in 80% of cases, according to the person correlation between good results with ultrasound and the control group.*

### Conclusion

Birth defects are also called birth defects, congenital disorders, or congenital anomalies. These are structural or functional abnormalities, such as metabolic disorders,

that occur during intrauterine life and are detected during pregnancy, childbirth, or later in life.

Intrauterine diagnosis of these defects by ultrasonography is valuable, as it allows to provide information regarding disease characteristics, progression, therapeutic possibilities, prognosis, risk of recurrence in future pregnancies, and prenatal counselling.

Once the diagnosis is made with certainty, it will be possible to choose to terminate the pregnancy in countries where abortion is legal or to schedule the birth in a highly complex center with cardiovascular facilities to receive the new-born and provide the required medical care immediately.
